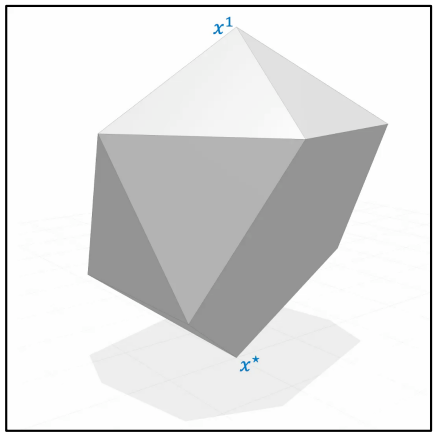
History of Linear Optimization ("LO" or "LP")

1947

Simplex Method

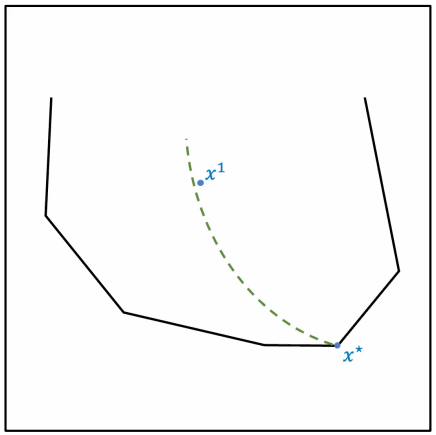
[George Dantzig, 1947]
75+ years ago



1984

Interior Point Method

[Narendra Karmarkar, 1984]
40 years ago



Simplex and IPMs require expensive matrix factorizations

Consider an LP instance with n decision variables and $\frac{n}{2}$ linear constraints, whose constraint matrix has sparsity = 0.05

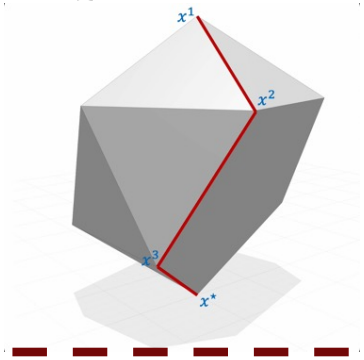
Number of variables (n)	Cost of one IPM iteration

Hence the emergence of FOMs for solving huge (and also not-so-huge) LP instances

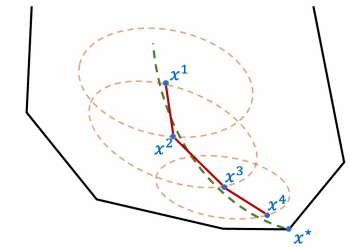
Recent Advances on Huge-Scale LP Solvers in the Industry

Classic methods

Simplex method



Interior-point method



First-order methods

- Primal-Dual Hybrid Gradient ("PDHG", "Chambolle-Pock method")
- Tackles huge-scale problems
- Benefits from modern computational architecture (such as GPU)

Google — 2021

COPT Cardinal Optimizer — State-of-art commercial optimization solver — February, 2024

NVIDIA — March, 2024

HiGHS — An open-source optimization software — March, 2024

FICO — State-of-art commercial optimization solver — April, 2024

GUROBI OPTIMIZATION — October, 2024

We are witnessing a dramatic shift from classic methods to first-order methods

- **Guarantees for PDHG for LP** using "Limiting Error Ratios" and LP Sharpness [Xiong and F 2023]
- **Guarantees for PDHG for CLP** – using level-set geometry
  [Xiong and F 2024]

This talk is based on material from three papers

For LP and conic optimization:

- New computational guarantees based on problem (sub)level-set geometry

Xiong, Z., and Freund, R. M. (2024). The Role of Level-Set Geometry on the Performance of PDHG for Conic Linear Optimization.

For LP with unique optima:

- Closed-form iteration bound
- Two-stage performance of PDHG
- "Average-case" polynomial-time complexity guarantee

Xiong, Z. (2024). Accessible Theoretical Complexity of the Restarted Primal-Dual Hybrid Gradient Method for Linear Programs with Unique Optima.

Xiong, Z. (2024). Probabilistic Analysis of Restarted PDHG for Linear Programming Problems (working paper).

Conic Linear Optimization ("CLO" or "CLP")

CLP in standard form

(primal)

$$\begin{aligned} \min\ & c^\top x \\ \text{s.t. } & Ax = b \\ & x \in \mathcal{K} \end{aligned}$$

(dual)

$$\begin{aligned} \max\ & b^\top y \\ \text{s.t. } & c - A^\top y \in \mathcal{K}^* \end{aligned}$$

Decision variables

- $x \in R^n$ (for primal problem)
- $y \in R^m$ (for dual problem)

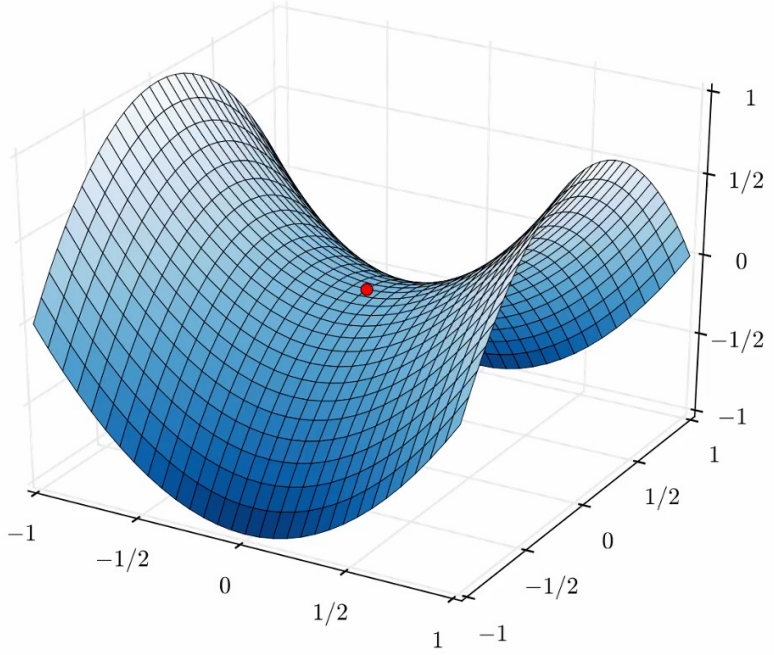
CLP saddlepoint formulation

$$\min_{x \in \mathcal{K}} \max_{y}\ c^\top x - y^\top A x + b^\top y$$

Primal-Dual Hybrid Gradient Method (PDHG)

Conic Optimiztion in Saddlepoint Form

$$\min_{x \in \mathcal{K}} \max_{y} \; c^\top x + b^\top y - y^\top A x$$



PDHG

$$x^{k+1} \leftarrow \text{Proj}_{\mathcal{K}}\left(x^k - \tau\left(c - A^\top y^k\right)\right)$$

Gradient w.r.t. x^k

$$y^{k+1} \leftarrow y^k + \sigma\left(b - A x^{k+1}\right) - \sigma A\left(x^{k+1} - x^k\right)$$

Gradient w.r.t. y^k Momentum Term

Primal-Dual Hybrid Gradient for Conic Optimization

PDHG

$$x^{k+1} \leftarrow \text{Proj}_{\mathcal{K}}\left(x^k - \tau\left(c - A^\top y^k\right)\right)$$
$$y^{k+1} \leftarrow y^k + \sigma\left(b - Ax^{k+1}\right) - \sigma A\left(x^{k+1} - x^k\right)$$

- **Inexpensive iterations**:
  Only requires matrix-vector multiplications
- **"Fast" convergence rates**:
  Adaptive restarts based on average iterates yield global linear convergence on LP [Applegate, Hinder, Lu, Lubin, 2023]

We use "PDHG" to denote "PDHG with adaptive restarts"

Motivation for Restarts for PDHG: "Visualization"

$$\min_{x} \max_{y} x \cdot y$$

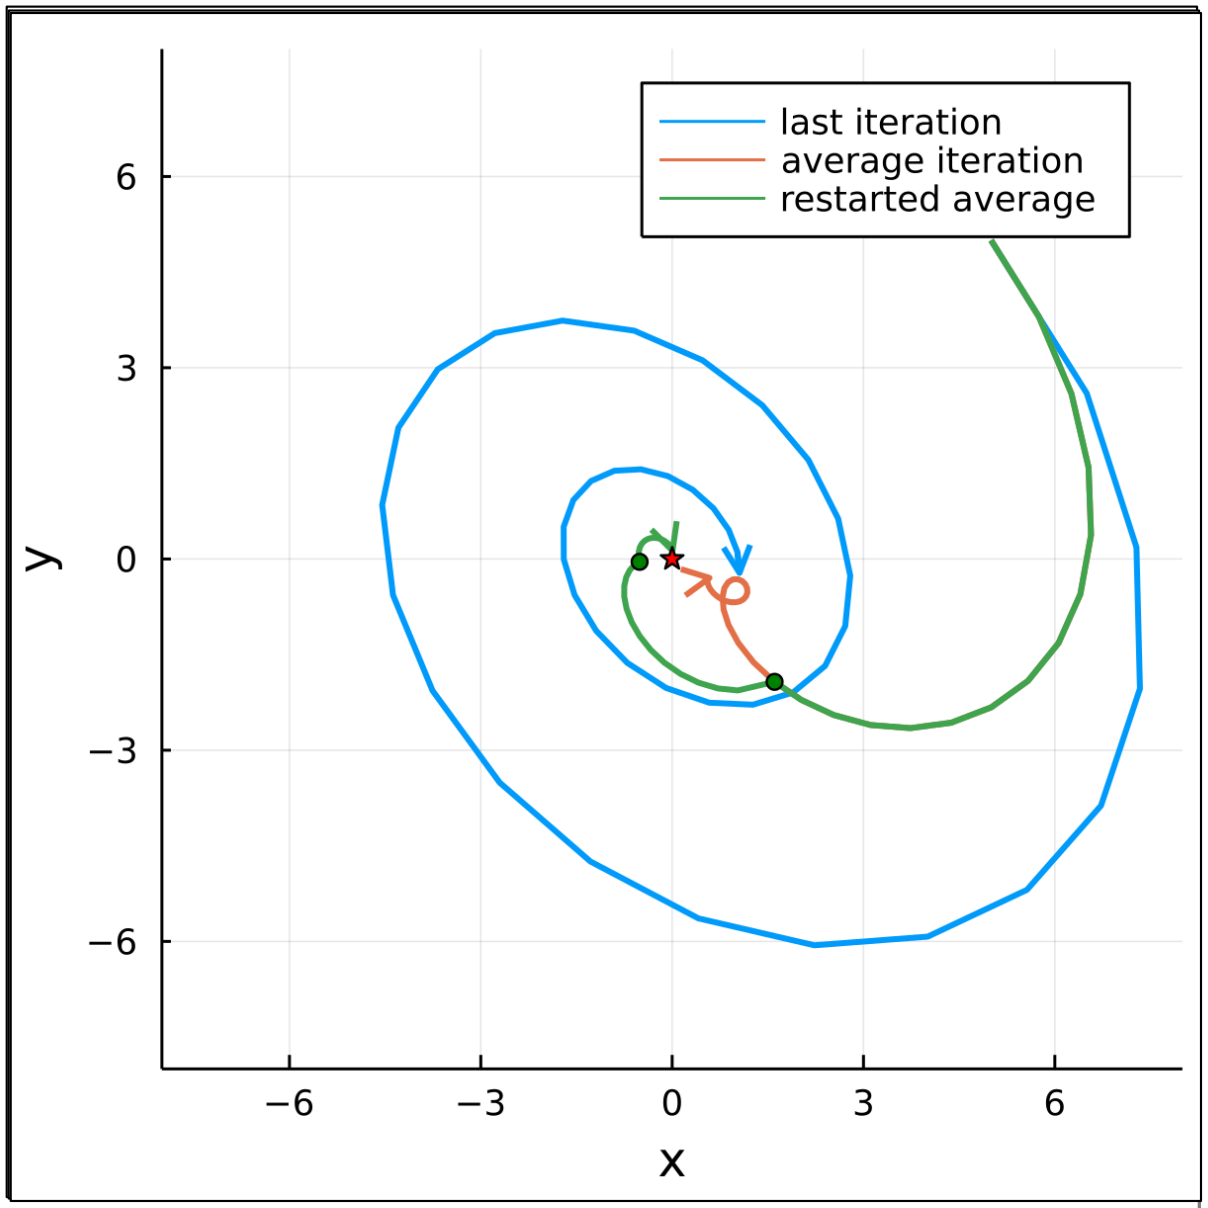


*figure courtesy Haihao Lu

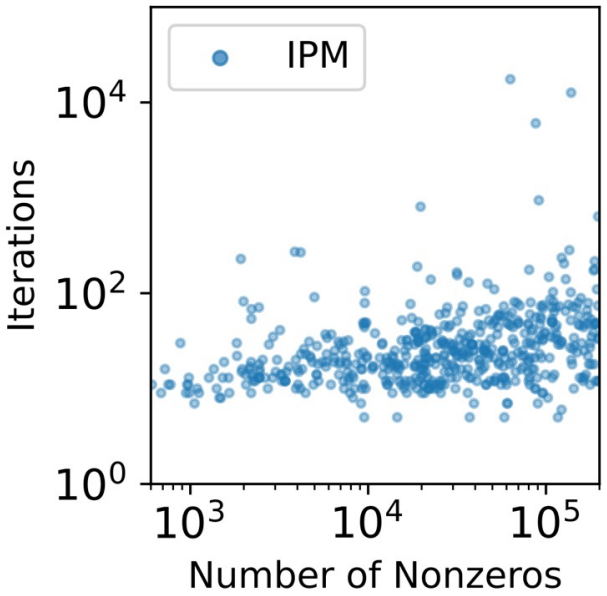
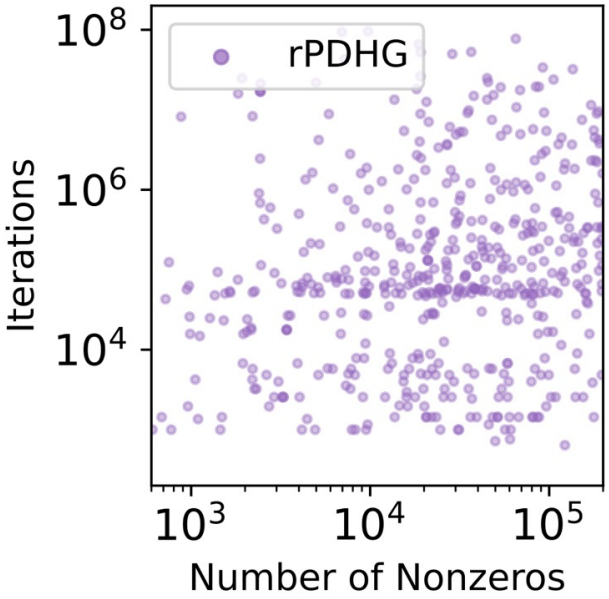
Challenge I: Variability in the Performance of PDHG

- PDHG uses many more iterations than an IPM
  makes sense, it is a first-order method … IPM iterations are hugely expensive while PDHG iterations are very cheap
- Some small problem instances require a very large number of PDHG iterations
  a real challenge for PDHG

IPM Iterations needed for
LP relaxations from MIPLIB 2017



PDHG iterations
LP relaxations from MIPLIB 2017



A seemingly easy LP instance

For $\gamma > 0$, define:

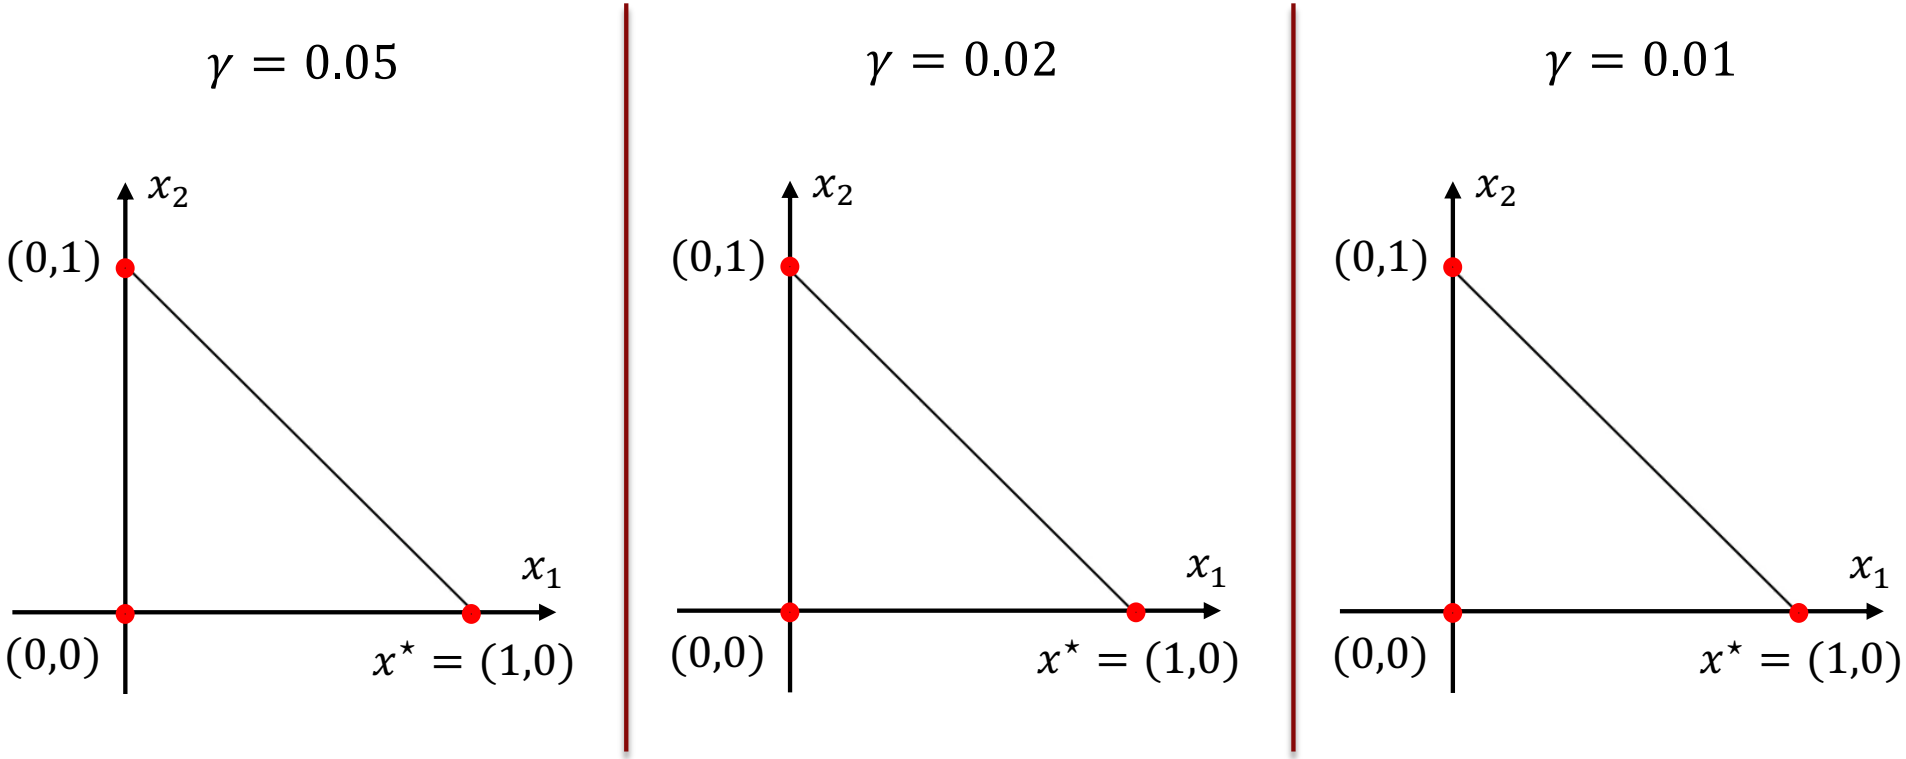
$$P(\gamma): \quad \min_{x_1, x_2} \; -(1+\gamma)x_1 - x_2$$
$$\text{s.t.} \quad x_1 + x_2 = 1$$
$$x_1 \geq 0, \; x_2 \geq 0$$

For $P(\gamma)$, the optimal solution is always $x^\star = (1,0)$

$P(\gamma)$ is always easy for the simplex method and interior-point methods

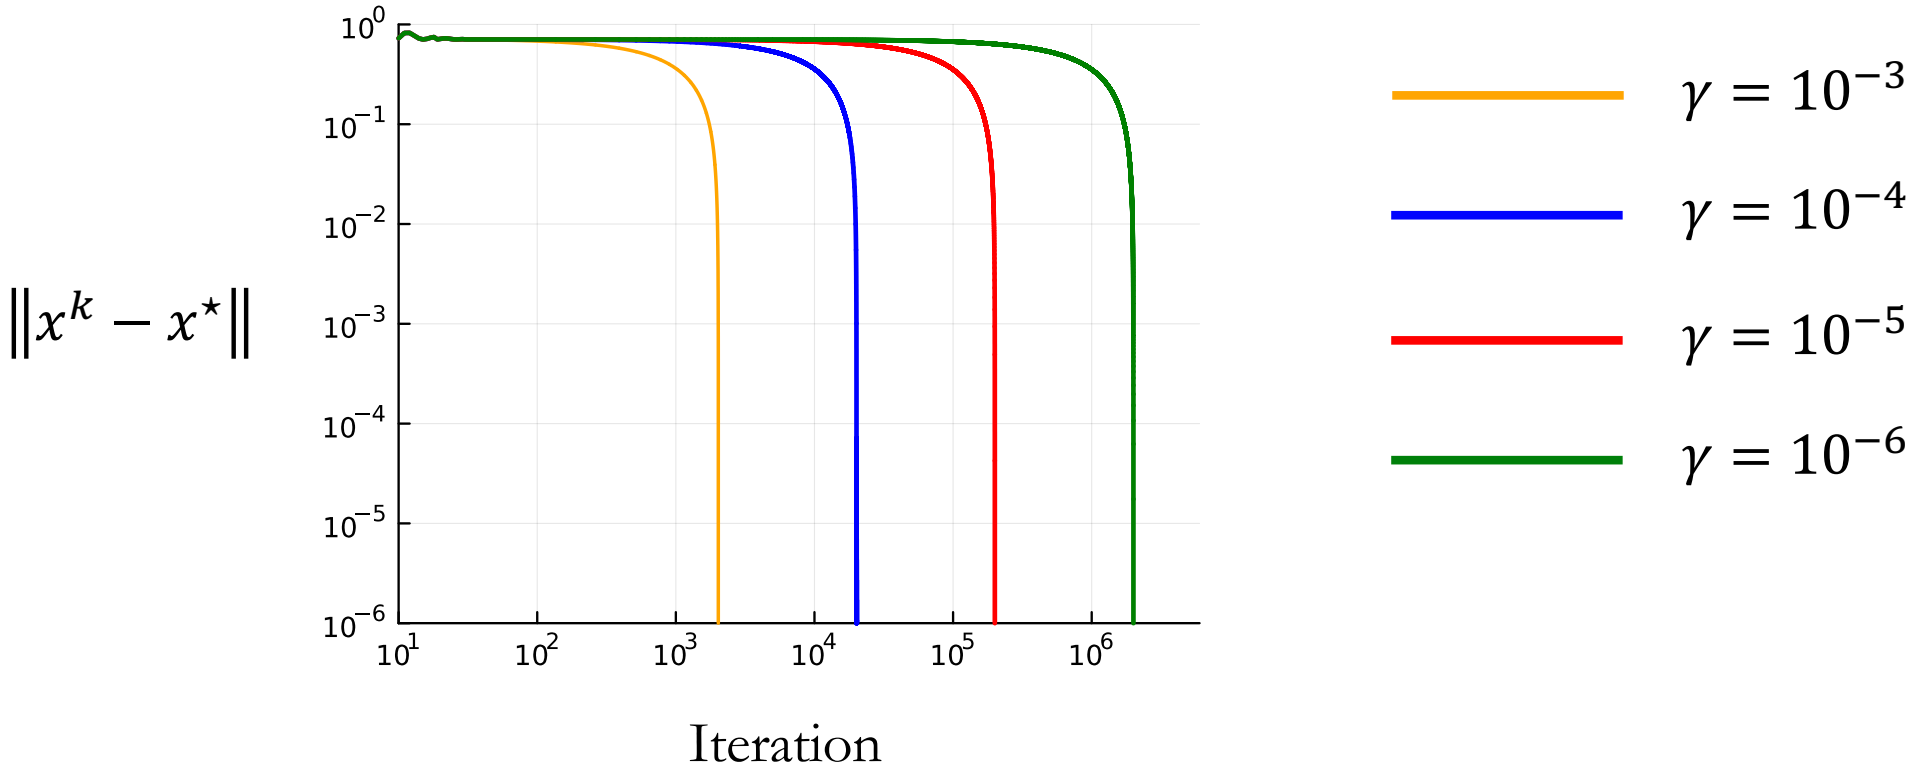
A seemingly easy LP instance

The trajectory of PDHG is as follows



1. The trajectory of PDHG is of course quite different from simplex or IPM.
2. The smaller the γ is, the slower the convergence will be.

A seemingly easy LP instance



When $\gamma = 10^{-6}$, PDHG requires more than 1,000,000 iterations.
What **conditions** of $P(\gamma)$ make it so hard for PDHG?

Challenge II: Loose/unworkable computational guarantees

Existing computational guarantees:

Theorem [Applegate, Hinder, Lu, Lubin, 2023] PDHG computes an ε-optimal solution within

$$O\left((\|x^\star\| + \|y^\star\|) \cdot \|A\| \cdot \boldsymbol{H(K)} \cdot \log\left(\frac{\|x^\star\| + \|y^\star\|}{\varepsilon}\right)\right)$$

iterations.

$\boldsymbol{H(K)}$ is the global Hoffman constant of the matrix K of the KKT system

$$K = \begin{pmatrix} A & \\ -A & \\ & A^\top \\ c^\top & -b^\top \end{pmatrix}, \quad H(K) \approx \frac{1}{\min\limits_{J \subseteq \{1,\ldots,2m+n+1\}} \sigma^+_{\min}(K_J)}$$

m: the number of constraints
n: the number of variables

1. **Usually too loose**
2. **Very hard to compute/validate/analyze**

Challenge II: Loose/unworkable computational guarantees

Theorem [Applegate, Hinder, Lu, Lubin, 2023] PDHG computes an ε-optimal solution within

$$O\left((\|x^\star\| + \|y^\star\|) \cdot ||A|| \cdot \boldsymbol{H(K)} \cdot \log\left(\frac{\|x^\star\| + \|y^\star\|}{\varepsilon}\right)\right)$$

iterations.

Key questions:

- What conditions of the problem actually drive the performance of PDHG? Sublevel-set Geometry
- Can we improve these conditions and so improve computational performance in theory/practice?
  Yes, by using Hessian rescaling (not covered in this talk)
- Can we shrink the gap between theory and practice?
  Yes, by using probabilistic average case analysis (if time permits…)

Challenge II: Loose/unworkable computational guarantees

Existing computational guarantees:

Theorem [Applegate, Hinder, Lu, Lubin, 2023] PDHG computes an ε-optimal solution within

$$O\left((\|x^\star\| + \|y^\star\|) \cdot \|A\| \cdot \boldsymbol{H(K)} \cdot \log\left(\frac{\|x^\star\| + \|y^\star\|}{\varepsilon}\right)\right)$$

iterations.

$\boldsymbol{H(K)}$ is the global Hoffman constant of the matrix $\boldsymbol{K}$ of the KKT system

$$\boldsymbol{K} = \begin{pmatrix} A & \\ -A & \\ & A^\top \\ c^\top & -b^\top \end{pmatrix} \qquad \boldsymbol{H(K)} \approx \frac{1}{\min\limits_{J \subseteq \{1,\ldots,2m+n+1\}} \sigma^+_{\min}(K_J)}$$

Likely way too loose, and very hard to compute/validate/analyze.

Challenge II: Loose/unworkable computational guarantees

Existing computational guarantees:

Theorem [Applegate, Hinder, Lu, Lubin, 2023] PDHG computes an ε-optimal solution within

$$O\left((\|x^\star\| + \|y^\star\|) \cdot \|A\| \cdot \boldsymbol{H(K)} \cdot \log\left(\frac{\|x^\star\| + \|y^\star\|}{\varepsilon}\right)\right)$$

iterations.

Key question:

- What conditions of the problem actually drive the performance of PDHG?

Sublevel-set Geometry

Sublevel-set geometry and new performance guarantees for PDHG

Primal-Dual Slack Space

Primal	Dual
$\min_{x} c^\top x$	$\max_{y,s} b^\top y$
s.t. $Ax = b$	s.t. $A^\top y + s = c$
$x \in \mathcal{K}$	$s \in \mathcal{K}^*$

The "primal-dual slack-space variable" is w :

$w := (x, s)$ are primal/dual feasible slacks

Duality gap: $\mathrm{Gap}(x, s) = c^\top x - b^\top y$

(which is a linear function of x and s)

The feasible primal-dual slack-space variables

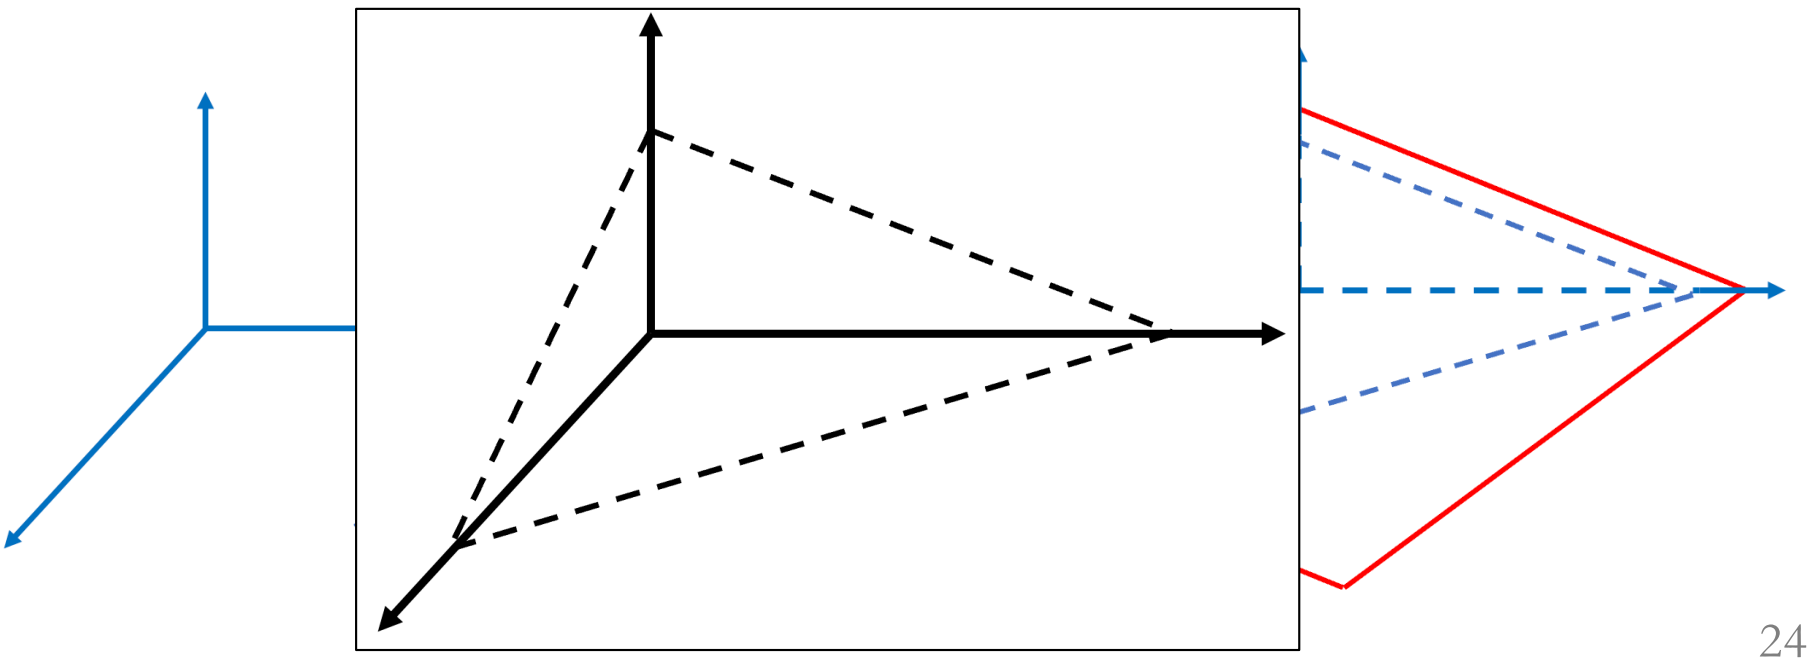
$$\min_{x} \; c^\top x \qquad \max_{y,s} \; b^\top y$$

s. t. $Ax = b$, $x \in \mathcal{K}$

s. t. $A^\top y + s = c$, $s \in \mathcal{K}^*$

(x, s) in the primal and dual cone for CLP

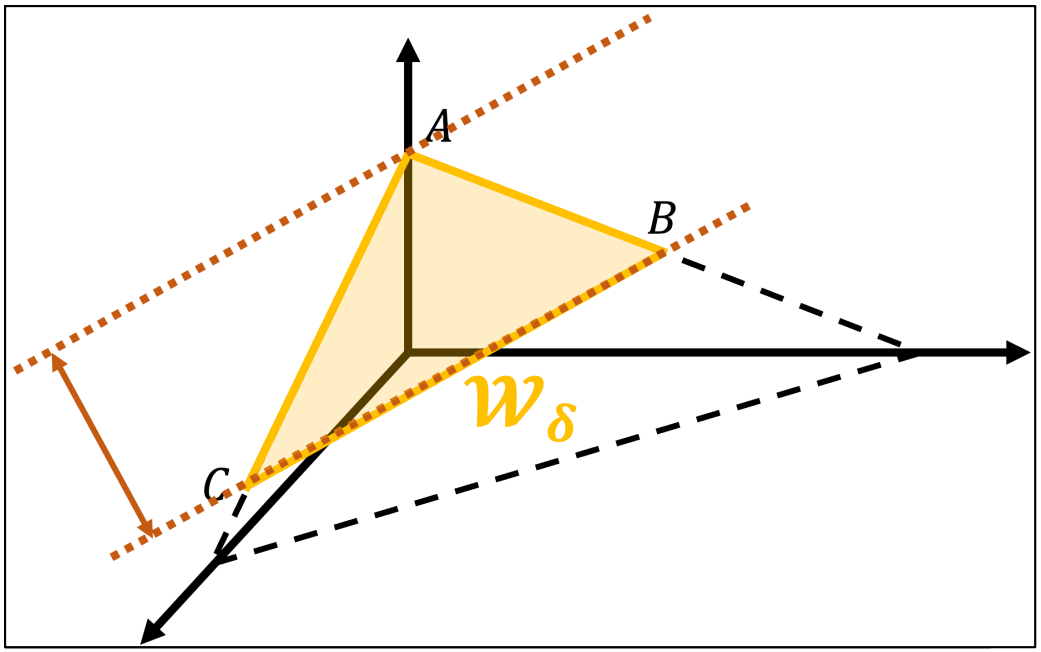
(x, s) lies in an affine subspace



Primal-Dual Slack Sublevel Set

$$\mathcal{W}_\delta := \left\{ w := (x, s) \;\middle|\; \begin{array}{c} w \text{ is primal/dual feasible} \\ \mathbf{Gap}(w) \leq \delta \end{array} \right\}$$

Note: $\mathcal{W}_0 = \mathcal{W}^\star$



Worst-case complexity of PDHG (under unique optima)

Theorem [Xiong and F 2024]: Suppose $w^\star$ is unique. PDHG computes an $\boldsymbol{\varepsilon}$-optimal solution within

$$\tilde{O}\left(\kappa \cdot \lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}} \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)$$

iterations.

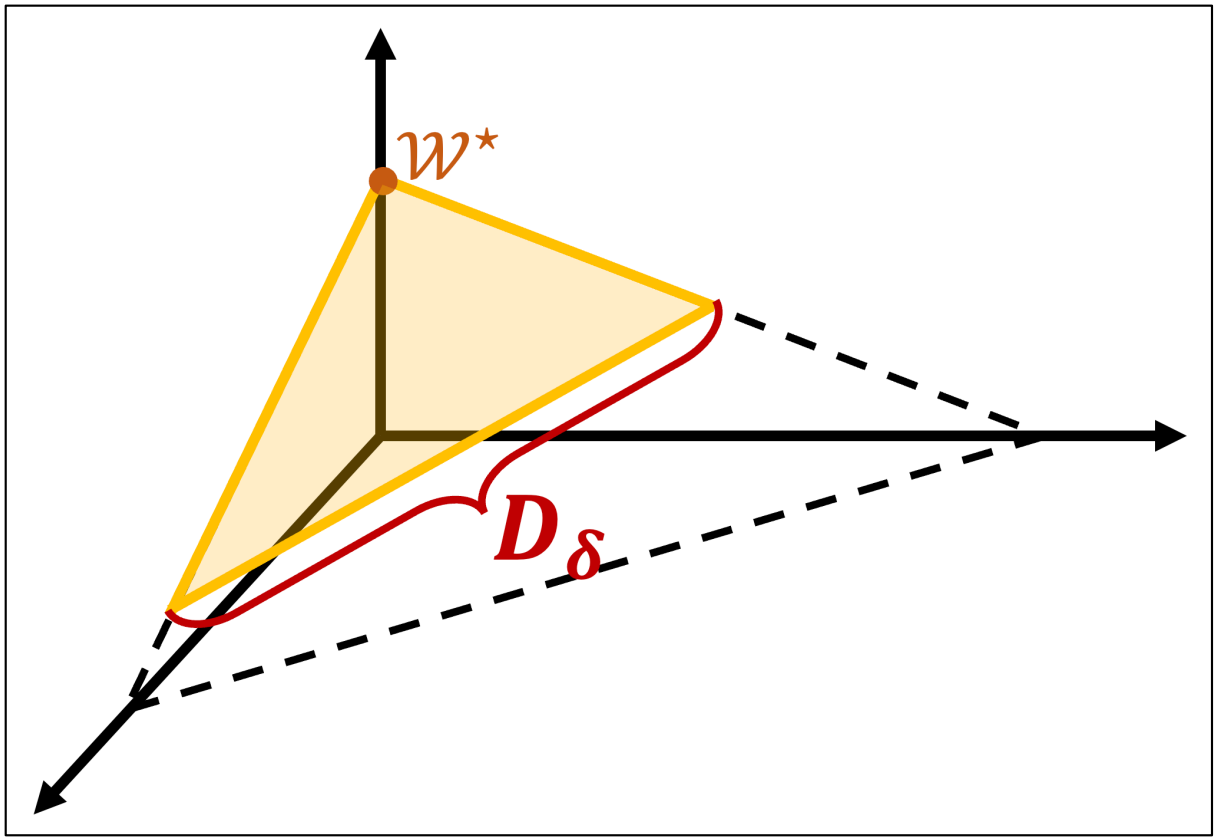
Matrix condition number of A:

$$\kappa := \sigma^+_{\max}(A)/\sigma^+_{\min}(A)$$

"Sublevel-set geometry"

D_δ: Diameter of δ-sublevel set $\mathcal{W}_\delta$

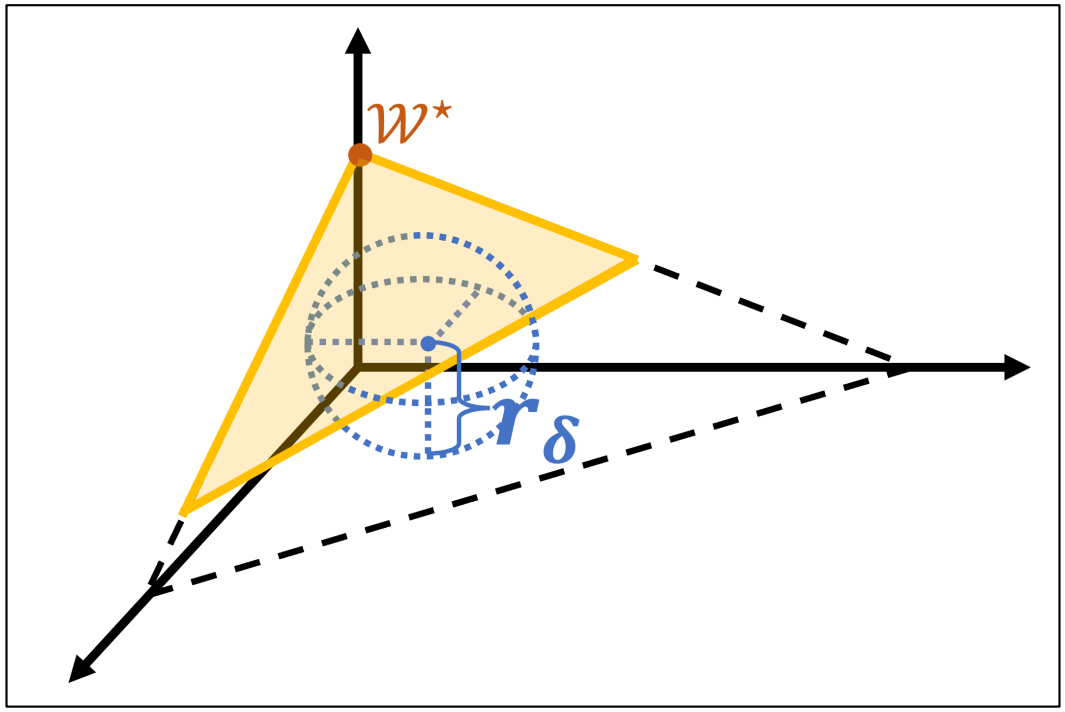
$$D_\delta := \max_{\bar{w}, \hat{w} \in \mathcal{W}_\delta} \|\bar{w} - \hat{w}\|$$



r_δ: "Conic Radius" of $\mathcal{W}_\delta$

$$r_\delta := \max_{r \geq 0,\, w \in \mathcal{W}_\delta} r$$
$$\text{s.t.} \quad B_w(r) \subset \mathcal{K} \times \mathcal{K}^*$$

r_δ is the radius of the maximum ball inscribed in $\mathcal{K} \times \mathcal{K}^*$ and centered at a point in $\mathcal{W}_\delta$



Target: ε-optimal solution

(x, s) is an $\boldsymbol{\varepsilon}$-optimal solution if:

- distance to each type of constraint is no larger than ε , and
- the duality gap is not larger than ε

(x, s) is an $\boldsymbol{\varepsilon}$-optimal solution if:

- $\mathrm{Dist}(x, \{x | Ax = b\}) \leq \varepsilon$
- $\mathrm{Dist}(x, \mathcal{K}) \leq \varepsilon$
- $\mathrm{Dist}(s, \{s | \exists\ y\ \ \mathrm{s.t.}\ A^\top y + s = c\}) \leq \varepsilon$
- $\mathrm{Dist}(s, \mathcal{K}^\star) \leq \varepsilon$
- $c^\top x - b^\top (AA^\top)^{-1} A(c - s) \leq \varepsilon$

Worst-case complexity of PDHG

Theorem [Xiong and F 2024]: Suppose $w^\star$ is unique. PDHG computes an $\boldsymbol{\varepsilon}$-optimal solution within

$$\tilde{O}\left(\kappa \cdot \lim_{\delta \to 0} \frac{D_\delta}{r_\delta} \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)$$

iterations.

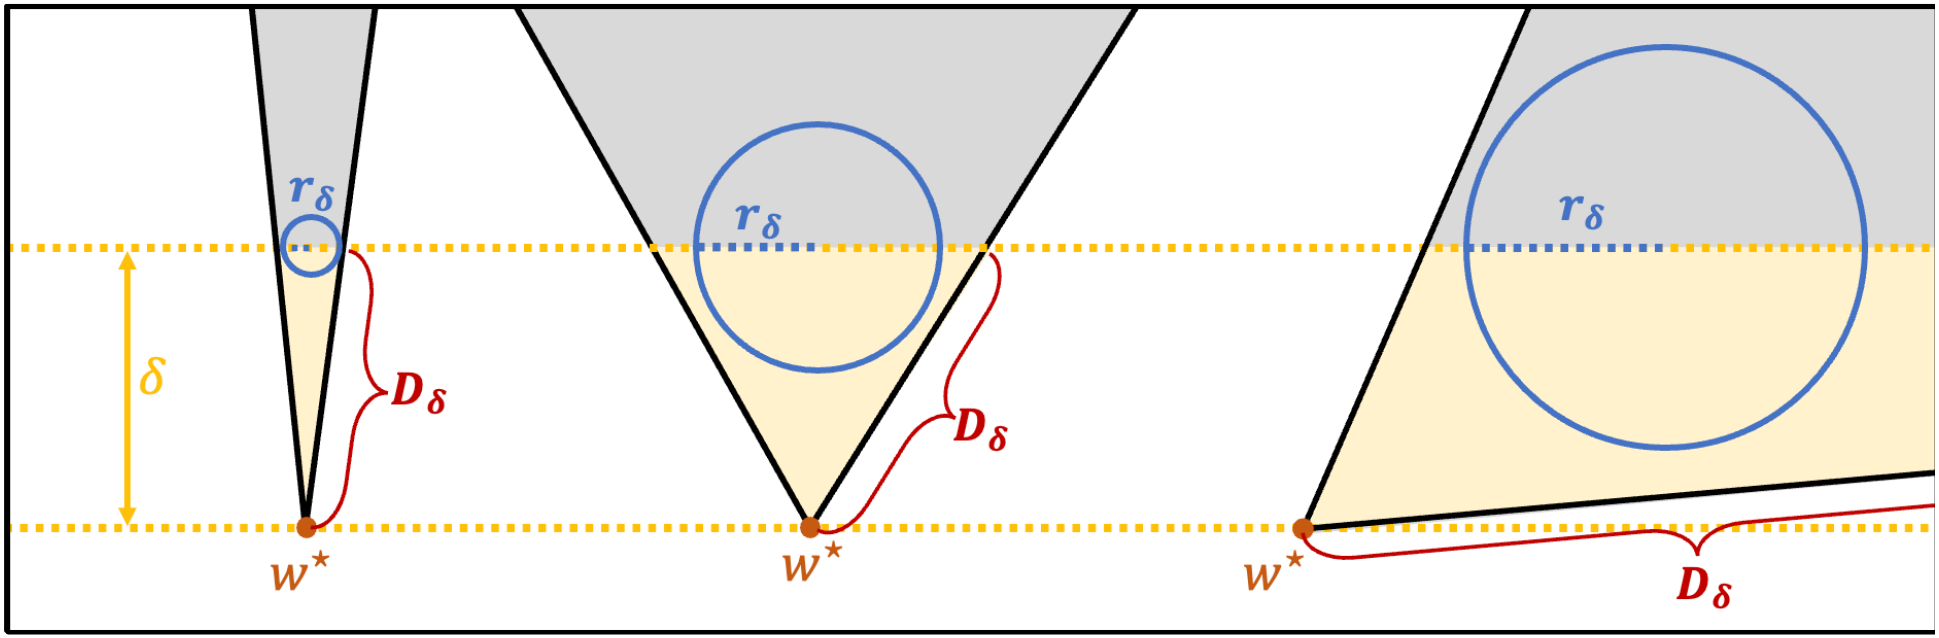
Matrix condition number of A:

$$\kappa := \sigma^+_{\max}(A)/\sigma^+_{\min}(A)$$

"Sublevel-set geometry"

Local Geometry of and $\lim_{\delta \to 0} \frac{D_\delta}{r_\delta}$ in the case of LP

When $w^\star$ is unique and δ is sufficiently small, $\mathcal{W}_\delta$ is a slice of a pointed cone at $w^\star$.



Very small r_δ
Intermediate D_δ

Intermediate r_δ
Intermediate D_δ

Intermediate r_δ
Very large D_δ

Worst-case complexity of PDHG (under unique optima)

Matrix condition number of A: $\kappa = \sigma^{+}_{\max}(A)/\sigma^{+}_{\min}(A)$

Theorem [Xiong and F 2024]: Suppose $w^\star$ is unique. PDHG computes an $\boldsymbol{\varepsilon}$-optimal solution within

$$\tilde{O}\left(\kappa \cdot \lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}} \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)$$

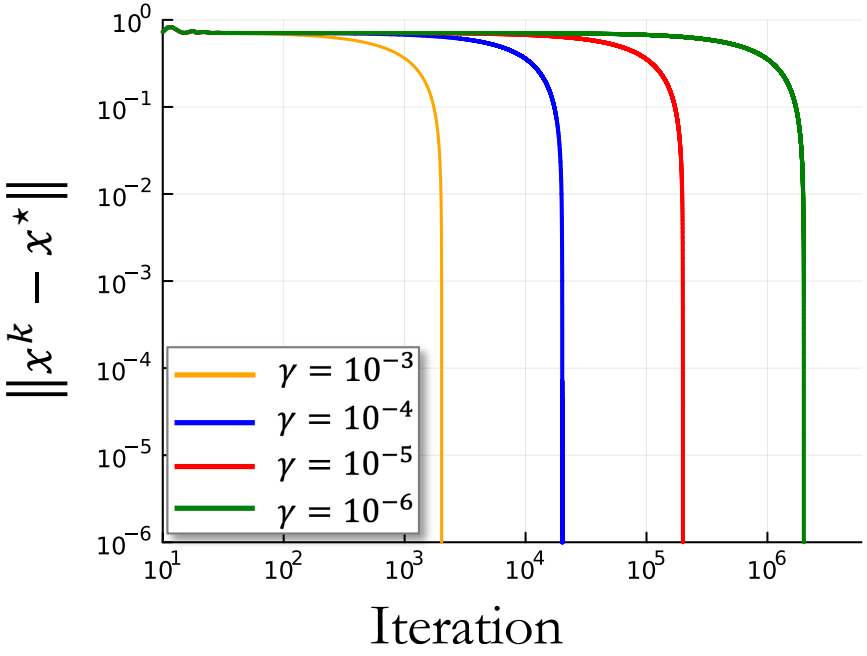
iterations.

Matrix condition number

Local geometric condition

Recall the $P(\gamma)$ example

$$P(\gamma): \quad \min_{x_1,x_2} \; -(1+\gamma)x_1 - x_2 \quad \text{s.t.} \quad x_1 + x_2 = 1, \quad x_1 \geq 0, \; x_2 \geq 0$$



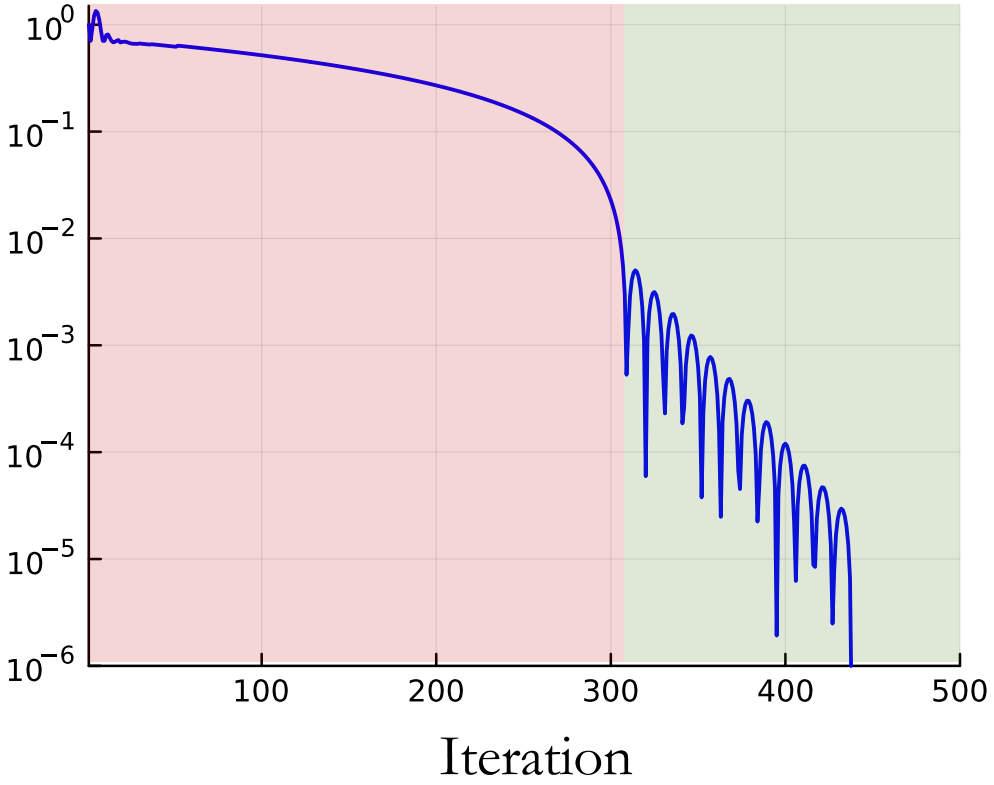
γ	Iteration count	$\lim_{\delta\to 0} \frac{D_\delta}{r_\delta}$
10^{-3}	2017	1414.2
10^{-4}	20023	14142.1
10^{-5}	200029	141421.4
10^{-6}	2000035	1414213.6

Observation: the number of iterations is linear in $\lim_{\delta\to 0} \frac{D_\delta}{r_\delta}$

The Observed Two-Stage Performance of PDHG

Typical convergence performance of PDHG

$\|w^k - w^\star\|$

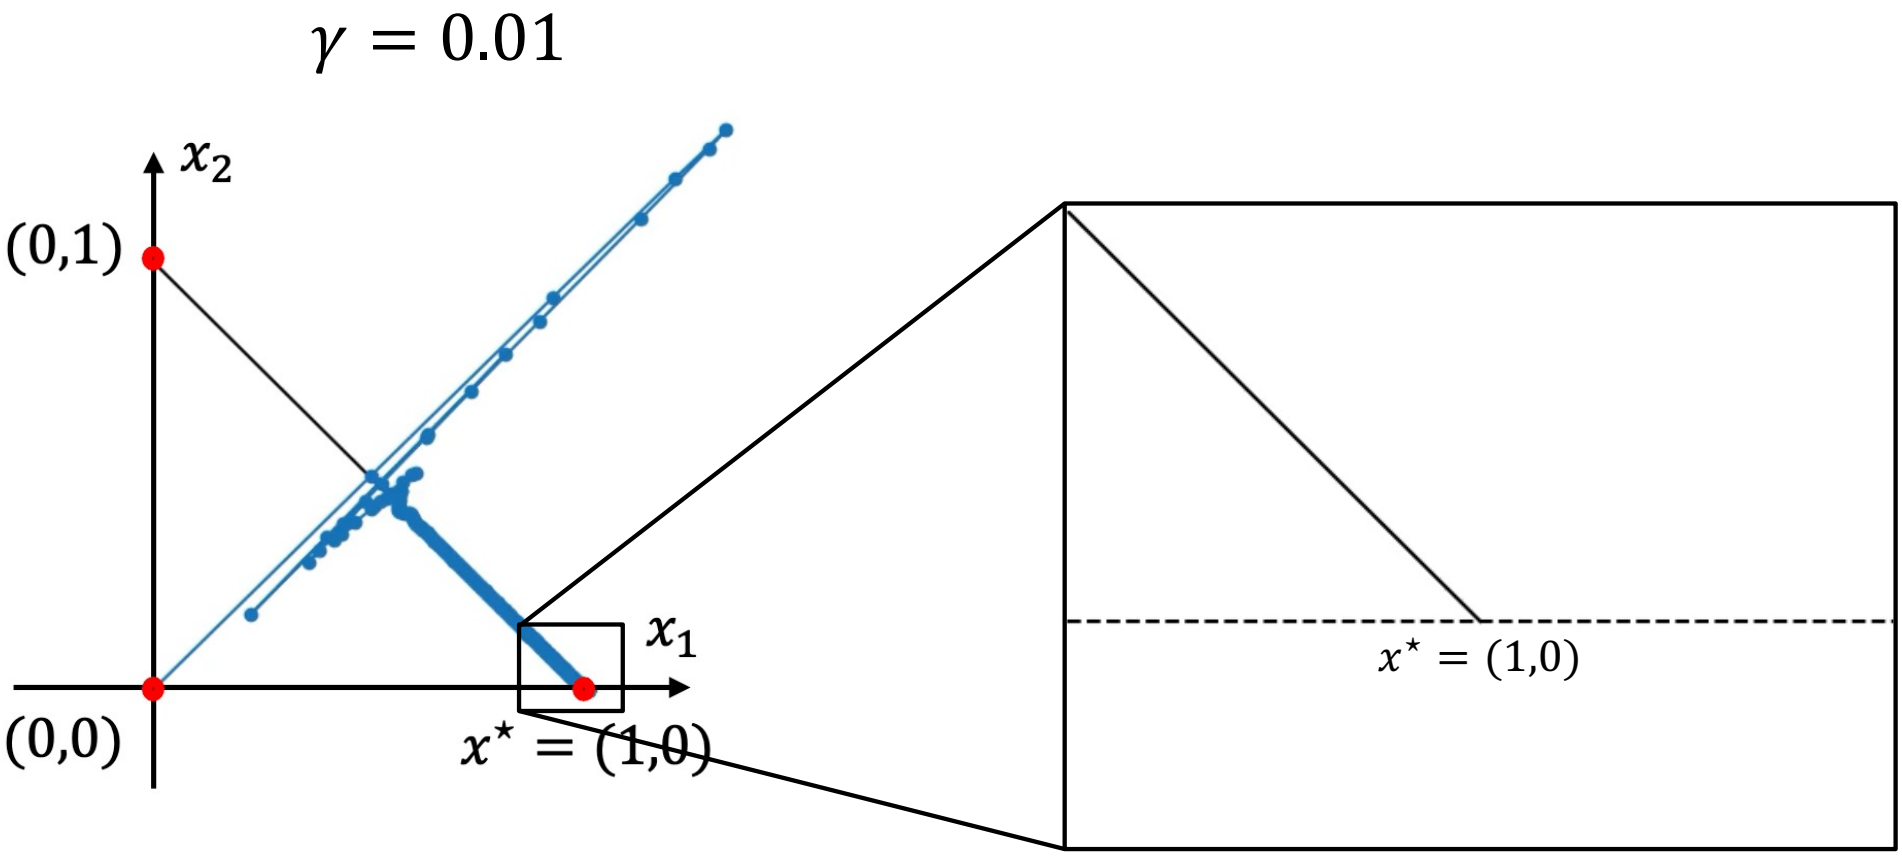


(in the case $\gamma = 0.01$)

Stage I:
Finite-time basis identification

Stage II:
Fast local convergence

The Observed Two-Stage Performance of PDHG



Stage I:
Finite-time basis identification

Stage II:
Fast local convergence

Two-Stage Performance of PDHG

Theorem (Stage I: Finite-time basis identification) [X, 2024a]:
The solution x^k identifies the optimal basis $\mathcal{B}$ (i.e. $\mathrm{supp}(x^k) = \mathcal{B}$) for all $k \geq T_{\mathrm{basis}}$, where:

$$T_{\mathrm{basis}} := \tilde{O}\left(\kappa \cdot \lim_{\delta \to 0} \frac{D_\delta}{r_\delta}\right)$$

Theorem (Stage II: Fast local convergence) [X, 2024a]:
After identifying the optimal basis, PDHG computes an $\boldsymbol{\varepsilon}$-optimal solution within additional

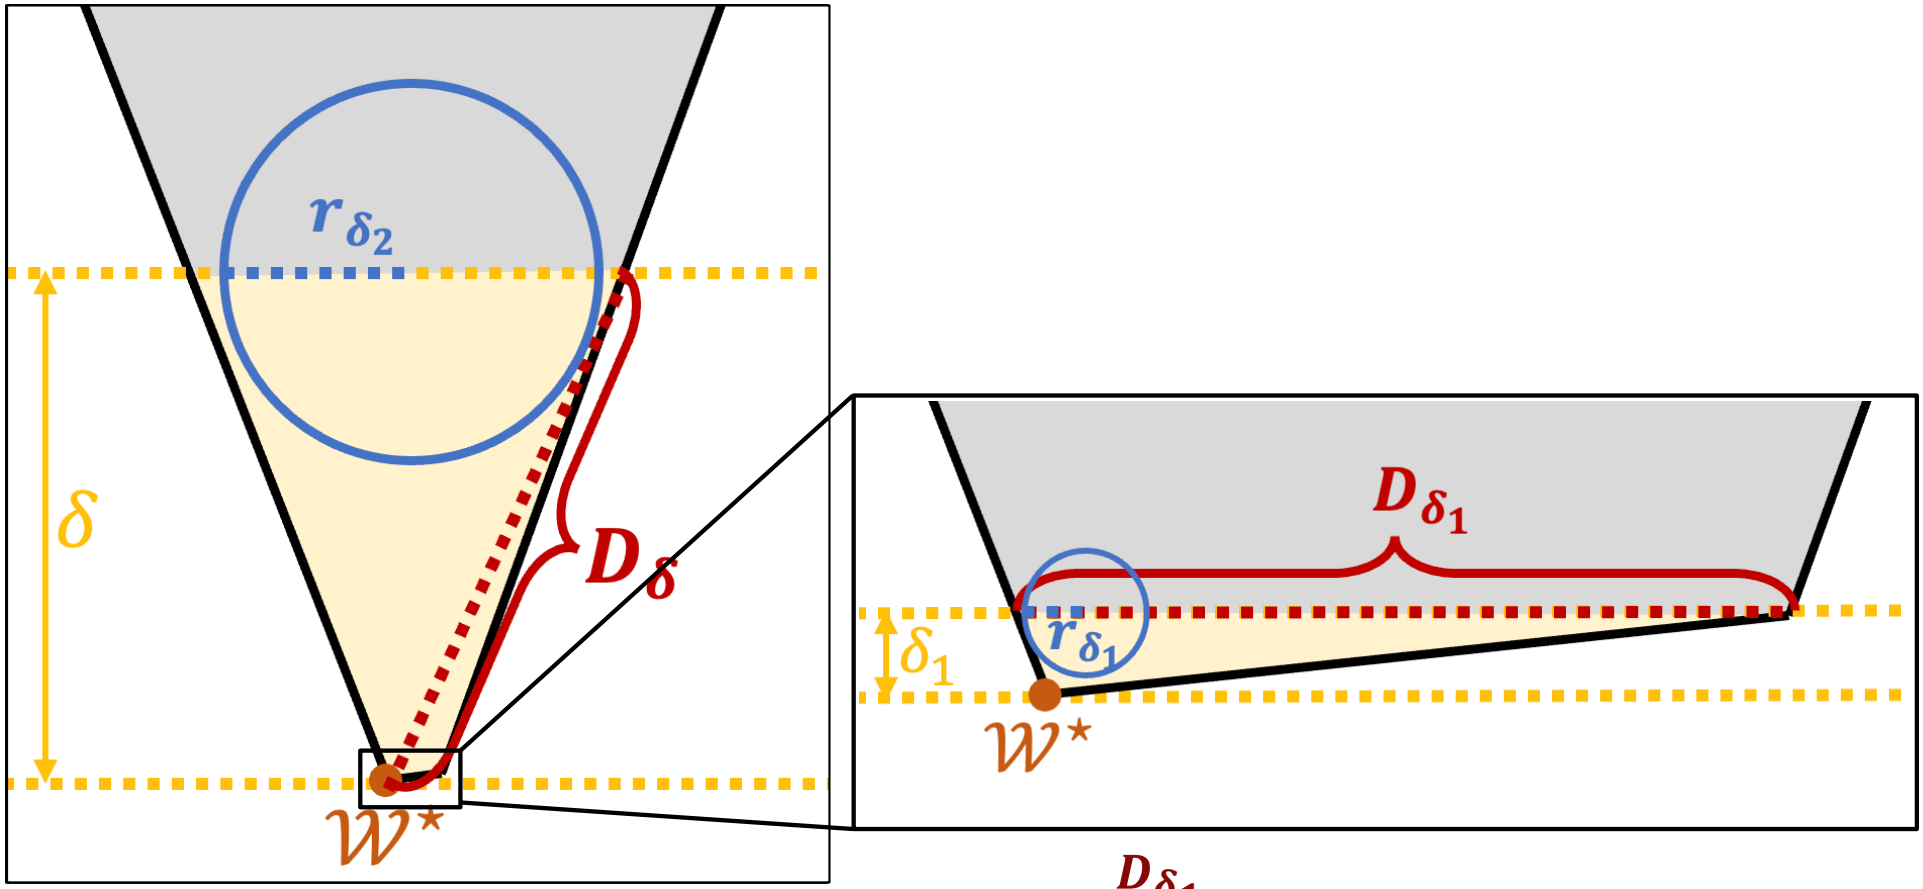
$$T_{\mathrm{local}} := \tilde{O}\left(\|B^{-1}\|\|A\| \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)$$

iterations.

$\|B^{-1}\|\|A\|$: Only matrix condition numbers.

Stage II converges faster because it is essentially just solving a system of equations…

Another example

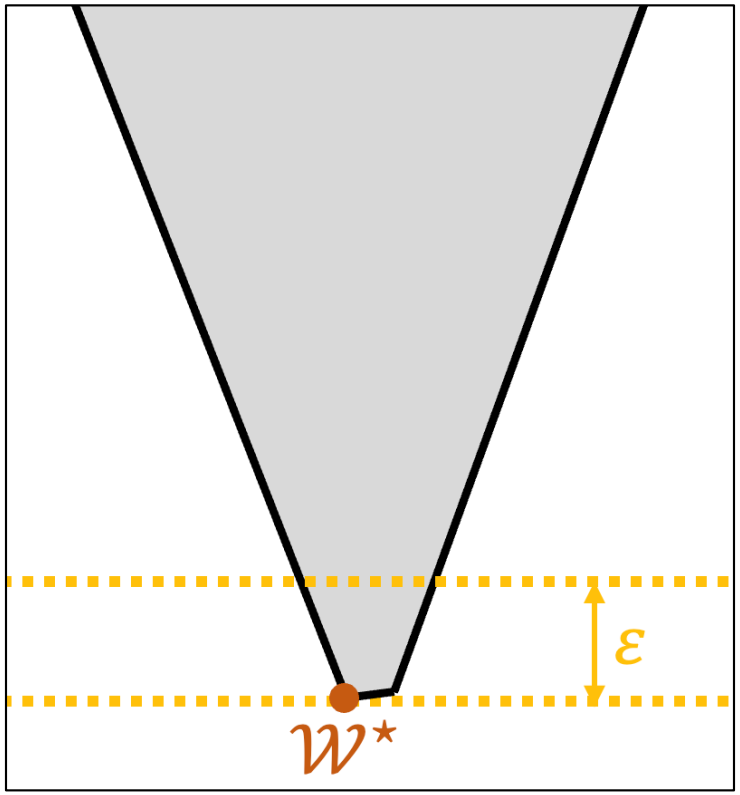


For $\delta_2 > \delta_1$, $\frac{D_{\delta_2}}{r_{\delta_2}}$ becomes smaller/better

$\frac{D_{\delta_1}}{r_{\delta_1}}$ is very large/bad (due to the small r_{δ_1})

Is $\lim_{\delta \to 0} \frac{D_\delta}{r_\delta}$ the only geometric condition?

Suppose we want an ε-optimal solution:



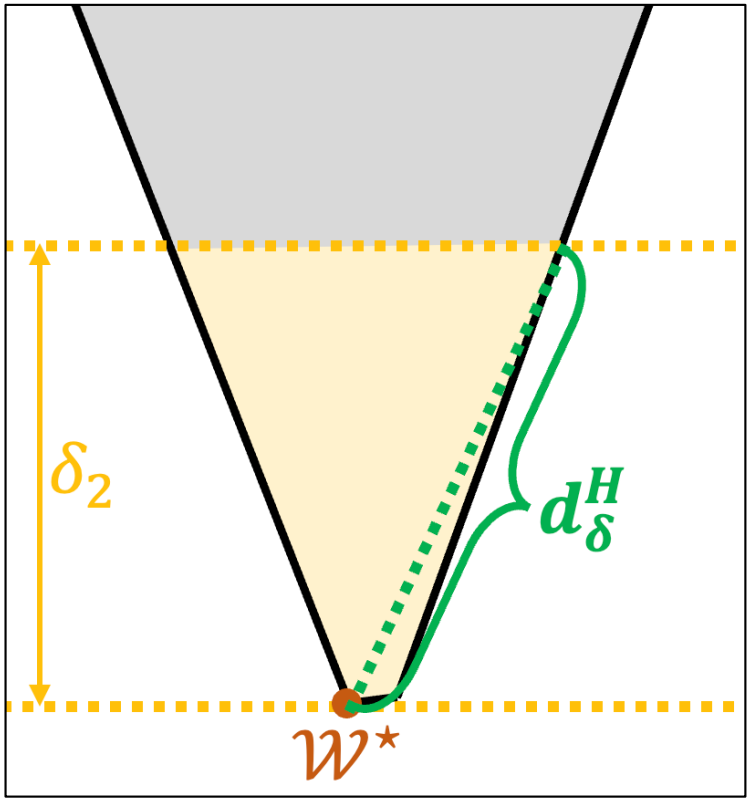
Intuition: The very-local bad geometry should not have a significant impact when the iterates of the algorithm have not yet reached the local neighborhood.

Is $\lim_{\delta \to 0} \frac{D_\delta}{r_\delta}$ the only geometric condition?

We will need a third geometric measure that is designed to capture the notion of the level set "being close to $\mathcal{W}^\star$"

$$d_\delta^H := \max_{w \in \mathcal{W}_\delta} \text{Dist}(w, \mathcal{W}^\star)$$

Hausdorff distance from $\mathcal{W}_\delta$ to $\mathcal{W}^\star$



Our General Conic Optimization Computational Guarantee

Theorem [Xiong and F 2024]: The number of PDHG iterations required to compute an $\boldsymbol{\varepsilon}$-optimal solution is upper bounded by:

$$\tilde{O}\left(\kappa \cdot \max\left\{\frac{D_\delta}{r_\delta} \cdot \ln\left(\frac{1}{\varepsilon}\right),\ \frac{d_\delta^H}{\varepsilon}(1 + \mathrm{Dist}(0, \mathcal{W}^\star))\right\}\right)$$

for each $\delta > 0$.

How good the geometry of $\mathcal{W}_\delta$ is

How close $\mathcal{W}_\delta$ is to $\mathcal{W}^\star$

Implication: If there is a δ-sublevel set that

(i) has good geometry and (ii) is close to the optimal solution set,

then PDHG may converge faster.

Remark: This result holds for LP with multiple optima, and for general conic optimization too.

D_δ: Diameter of … r_δ: Conic radius of … d_δ^H : Hausdorff distance …

Our General Conic Optimization Computational Guarantee

Theorem [Xiong and F 2024]: The number of PDHG iterations required to compute an $\boldsymbol{\varepsilon}$-optimal solution is upper bounded by:

$$\tilde{O}\left(\kappa \cdot \max\left\{\frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}} \cdot \ln\left(\frac{1}{\varepsilon}\right),\ \frac{\boldsymbol{d_\delta^H}}{\varepsilon}(1 + \mathrm{Dist}(0, \mathcal{W}^\star))\right\}\right)$$

for each $\delta > 0$.

Small when $\mathcal{W}_\delta$ has good geometry

Small when $\mathcal{W}_\delta$ is close to $\mathcal{W}^\star$

Q: Can we improve $\frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}}$ and $\boldsymbol{d_\delta^H}$?

A: Yes, by using Hessian Rescaling

$\boldsymbol{D_\delta}$: Diameter of … $\boldsymbol{r_\delta}$: Conic radius of … $\boldsymbol{d_\delta^H}$: Hausdorff distance …

Consider the generic case of LP: LPs with unique optima

Matrix condition number of A: $\kappa = \sigma^{+}_{\max}(A)/\sigma^{+}_{\min}(A)$

Theorem [Xiong and F 2024]: Suppose $w^\star$ is unique. PDHG computes an $\boldsymbol{\varepsilon}$-optimal solution within

$$\tilde{O}\left(\kappa \cdot \lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}} \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)$$

iterations.

Matrix condition number | Local geometric condition

[Xiong, 2024]:

- This bound has a closed-form expression
- PDHG has local fast convergence in a small neighborhood of $w^\star$
- This bound is $\tilde{O}\left(n^{2.5} \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)$ with high probability

Establishing "Average-case" performance guarantees

Probabilistic Analysis to shrink the gap between worst-case analysis and computational practice

	Worst-case complexity	Average-case complexity
Simplex Method	Exponentially poor [Klee and Minty, 1972]	$O(n^2)$ Borgwardt, Smale, Blair, Adler, Haimovich, Todd, Megiddo, et al. (~1980s)
Interior Point Method	$O(\sqrt{n}L)$ "Bit-length" L might be huge (~1980s)	$O(\sqrt{n} \cdot \ln n)$ Todd, Ye, Anstreicher, Potra et al. (~1990s)
PDHG	Exponentially poor	$\tilde{O}(n^{2.5})$ **with high probability** **[X, 2024b]**

Note: I have not seen any other results showing that first-order methods for LP can achieve polynomial-time complexity with high probability.

Iterations Bounds in Closed Form of the Optimal Basis/Solution

A formula for $\lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}}$ using the optimal basis/solution

Strict Complementary Slackness (under unique optima):
Let $\mathcal{B} := \text{supp}(x^\star)$ and $\mathcal{N} := \text{supp}(s^\star)$. Then $(\mathcal{B}, \mathcal{N})$ is a partition of $\{1,2,\dots,n\}$.

We use "$\approx$" to denote being equivalent up to an absolute constant (2).

Lemma [Xiong 2024]
Under unique optima, let $B := A_{\mathcal{B}}$, $N := A_{\mathcal{N}}$. Then

$$\lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}} \approx (\|x^\star\|_1 + \|s^\star\|_1) \cdot \max\left\{ \max_{i \in [m]} \frac{\|(B^{-1}N)_{i,:}\| + 1}{x^\star_{\mathcal{B}(i)}}, \max_{j \in [n-m]} \frac{\|(B^{-1}N)_{:,j}\| + 1}{s^\star_{\mathcal{N}(j)}} \right\}.$$

ℓ_1-norm of the optimal solution

$$= \max_i \left(\frac{1 + \text{norm of the } i\text{−th row of } (B^{-1}N)}{i\text{−th component of } x^\star_{\mathcal{B}}} \right)$$

$$= \max_j \left(\frac{1 + \text{norm of the j−th column of } (B^{-1}N)}{\text{j−th component of } s^\star_{\mathcal{N}}} \right)$$

$B^{-1}A = (I, B^{-1}N)$ is the simplex method tableau

A formula for $\lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}}$ using the optimal basis/solution

Strict Complementary Slackness:

Let $\mathcal{B} := \text{supp}(x^\star)$ and $\mathcal{N} := \text{supp}(s^\star)$. Then $(\mathcal{B}, \mathcal{N})$ is a partition of $\{1,2,\dots,n\}$.

We use "$\approx$" to denote being equivalent up to an absolute constant (2).

Lemma [Xiong 2024]

Under unique optima, let $B := A_{\mathcal{B}}$, $N := A_{\mathcal{N}}$. Then

$$\lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}} \approx (\|x^\star\|_1 + \|s^\star\|_1) \cdot \max\left\{ \max_{i \in [m]} \frac{\|(B^{-1}N)_{i,:}\| + 1}{x^\star_{\mathcal{B}(i)}}, \max_{j \in [n-m]} \frac{\|(B^{-1}N)_{:,j}\| + 1}{s^\star_{\mathcal{N}(j)}} \right\}.$$

Furthermore, $\lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}}$ has a simple upper bound:

$$\lim_{\delta \to 0} \frac{\boldsymbol{D_\delta}}{\boldsymbol{r_\delta}} \leq 2 \cdot \frac{\|x^\star\|_1 + \|s^\star\|_1}{\min_{i \in [n]} x_i^\star + s_i^\star} \cdot \|B^{-1}A\|$$

Ratio of ℓ_1-norm to the smallest nonzero

Norm of the simplex tableau at the optimal solution

An iteration bound using the optimal basis/solution

Theorem [Xiong 2024]: PDHG computes an $\boldsymbol{\varepsilon}$-optimal solution within:

$$\tilde{O}\left(\kappa \cdot \frac{\|x^\star\|_1 + \|s^\star\|_1}{\min\limits_{i\in[n]} x_i^\star + s_i^\star} \cdot \|B^{-1}A\| \cdot \ln\left(\frac{1}{\boldsymbol{\varepsilon}}\right)\right)$$

iterations.

The smallest nonzero $\left(\min\limits_{i\in[n]} x_i^\star + s_i^\star\right)$ plays a key role in other methods as well:

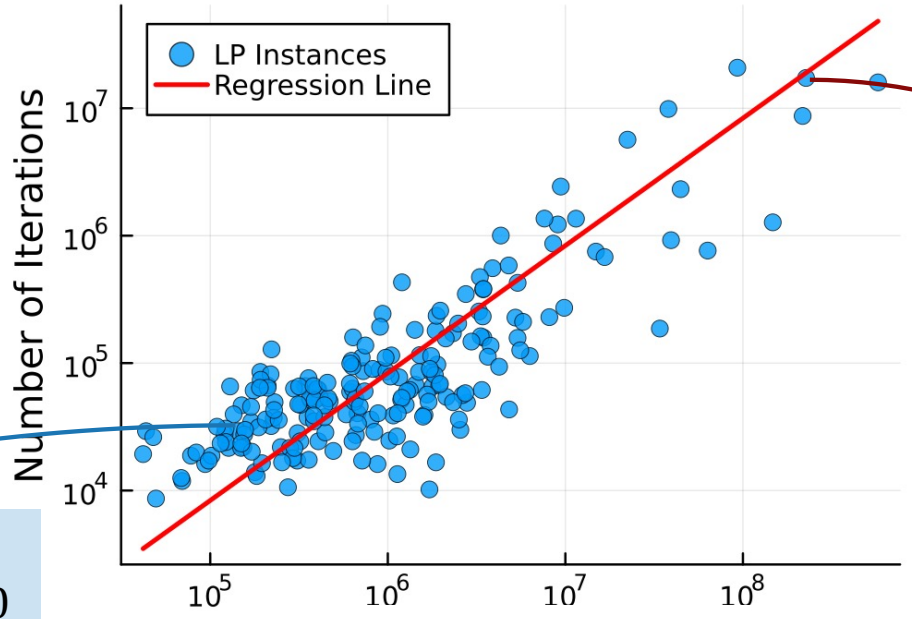
[Güler and Ye, 1993] [Ye, 1992] [Mehrotra and Ye, 1993] [Ye, 2011] …

The product of $\left(\frac{\|x^\star\|_1+\|s^\star\|_1}{\min\limits_{i\in[n]} x_i^\star+s_i^\star}\right)$ and a norm of $B^{-1}A$ also appears in IPM complexity:

[Potra, 1994][Anstreicher, Ji, Potra and Ye, 1999] …

Validation Experiments on random LP instances

Iterations Required to solve LP instance to $\varepsilon = 10^{-8}$



200 random LP instances with $\mathrm{m} = 60, \text{and } \mathrm{n} = 120$

Regression line: $\log_{10}(\text{PDHG Iteration}) = \log_{10} \kappa\Phi - 1.078$

1. Fairly obvious linear dependence on $\kappa \cdot \lim_{\delta \to 0} \frac{D_\delta}{r_\delta}$

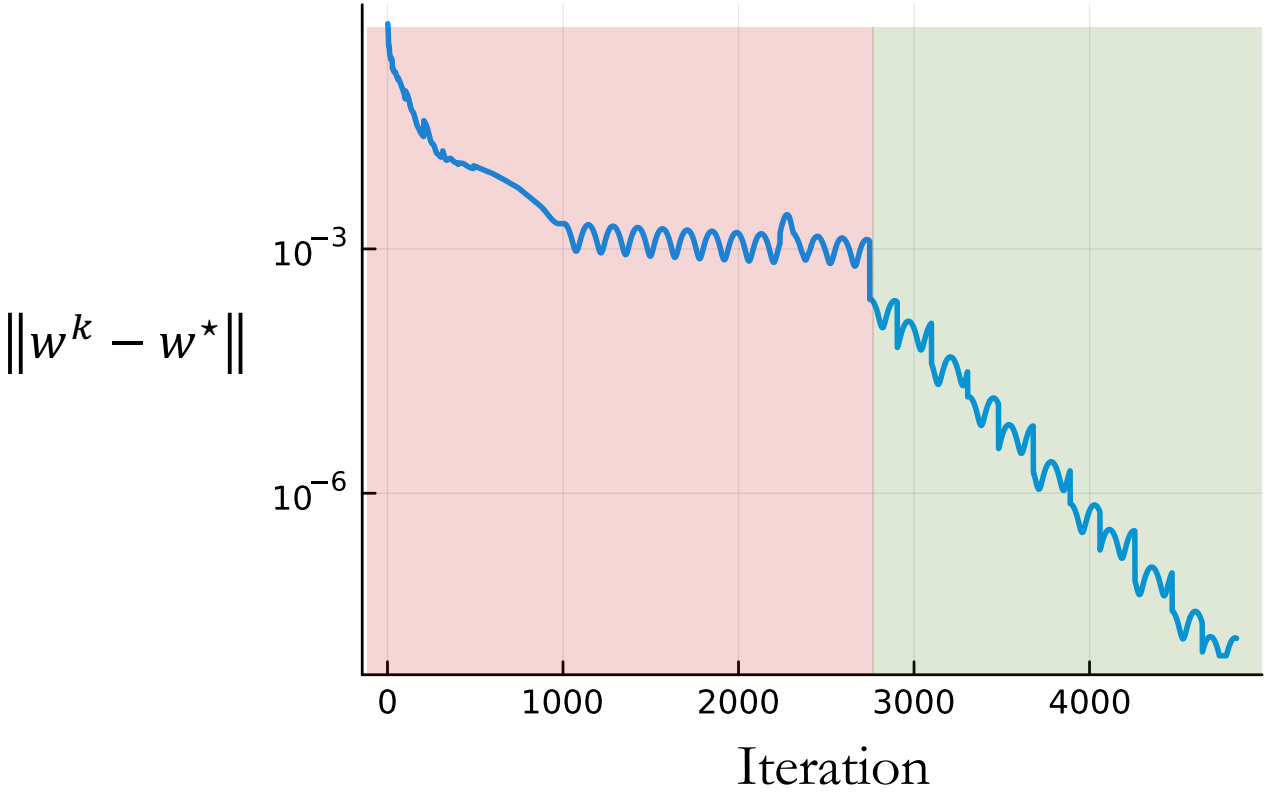
2. Although $\kappa \cdot \lim_{\delta \to 0} \frac{D_\delta}{r_\delta}$ can be extremely large in practice (or not), the random LP instances typically have smaller values of $\kappa \cdot \lim_{\delta \to 0} \frac{D_\delta}{r_\delta}$. More on this later…

Regarding the two-stage performance of PDHG on LP instances with unique optima

Two-Stage Performance of PDHG

Two-stage performance of PDHG on general LP [Lu and Yang 2023]

Typical convergence performance of PDHG



Stage I:
Finite-time basis identification

Stage II:
Fast local convergence

Two-Stage Performance of PDHG (under unique optima)

Theorem (Stage I: Finite-time basis identification) [Xiong 2024]:
Let $w^k = (x^k, s^k)$ denote the k-th iteration solution. The solution x^k identifies the optimal basis $\mathcal{B}$ (i.e. $\text{supp}(x^k) = \mathcal{B}$) for all $k \geq T_{\text{basis}}$, where :

$$T_{\text{basis}} := \tilde{O}\left(\kappa \cdot \lim_{\delta \to 0} \frac{D_\delta}{r_\delta}\right)$$

Theorem (Stage II: Fast local convergence)[Xiong 2024]:
Once the optimal basis has been determined, PDHG computes an $\boldsymbol{\varepsilon}$-optimal solution within an additional

$$T_{\text{local}} := \tilde{O}\left(\|B^{-1}\|\|A\| \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)$$

iterations.

$\|B^{-1}\|\|A\|$: Only matrix condition numbers.

Stage II converges faster because it is not affected by the sublevel set geometry

Can we explain the practical performance of PDHG using high-probability complexity analysis?

Todd's Classic Random LP Model

Definition (Random LP Model):

Select $\mathcal{B} \subset [n]$, and $|\mathcal{B}| = m$ and the solution $(\hat{x}, \hat{s})$ is distributed as follows:

$$\hat{x}_{\mathcal{B}} \sim |\mathcal{N}(0,1)|^m, \qquad \hat{x}_{\mathcal{N}} = 0,$$
$$\hat{s}_{\mathcal{B}} = 0, \qquad \hat{s}_{\mathcal{N}} \sim |\mathcal{N}(0,1)|^{n-m},$$

The random LP of the above optimal solution is distributed as follows:

$$A \sim \mathcal{N}(0,1)^{m \times n}, \qquad b = A\hat{x}, \qquad c = \hat{s}.$$

From a classic random LP model of [Todd, 1991].
Variants studied for IPM [Ye, 1994], [Anstreicher et al., 1999]
We use unit variance for simplicity of result.

This LP model has unique optima with probability = 1

Two-Stage Performance of PDHG

Theorem (Stage I: Finite-time basis identification) [Xiong 2024]:
Let T_{basis} denote the number of PDHG iterations to identify the optimal basis. Then it holds for any $\delta \in \left(\frac{1}{2^{c_0 n}}, 1\right)$ that

$$\mathbb{P}\left[T_{\text{basis}} \leq \tilde{O}\left(\frac{n^{2.5}}{\delta}\right)\right] \geq 1 - \delta.$$

Theorem (Stage II: Fast local convergence) [Xiong 2024]:
After T_{basis} iterations, let T_{local} denote the number of additional PDHG iterations to compute an $\boldsymbol{\varepsilon}$-optimal solution. Then it holds for any $\delta \in (0,1)$ that

$$\mathbb{P}\left[T_{\text{local}} \leq \tilde{O}\left(\frac{n}{\delta} \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)\right] \geq 1 - \delta.$$

Faster local linear convergence indicated by the probabilistic analysis.

Theorem (Stage I: Finite-time basis identification) [Xiong 2024]:
Let T_{basis} denote the number of PDHG iterations to identify the optimal basis. Then it holds for any $\delta \in \left(\frac{1}{2^{c_0 n}}, 1\right)$ that

$$\mathbb{P}\left[T_{\text{basis}} \leq \tilde{O}\left(\frac{n^{2.5}}{\delta}\right)\right] \geq 1 - \delta.$$

Theorem (Stage II: Fast local convergence) [Xiong 2024]:
After T_{basis} iterations, let T_{local} denote the number of additional PDHG iterations to compute an $\boldsymbol{\varepsilon}$-optimal solution. Then it holds for any $\delta \in (0,1)$ that

$$\mathbb{P}\left[T_{\text{local}} \leq \tilde{O}\left(\frac{n}{\delta} \cdot \ln\left(\frac{1}{\varepsilon}\right)\right)\right] \geq 1 - \delta.$$

This provides a possible explanation for why PDHG works well in practice (polynomial-time in most cases), even though $\kappa \cdot \lim_{\delta \to 0} \frac{D_\delta}{r_\delta}$ may take extreme values in the worst case.

But PDHG bound has a heavier tail compared with the two classic methods:

- PDHG has polynomial high-probability complexity
- IPM has polynomial average-case complexity. [Anstreicher, et al., 1999]

Summary/Remarks

- The convergence rate of PDHG for conic optimization is related to the geometry of primal-dual sublevel sets measured with D_δ, r_δ, d_δ^H
- For LP instances with unique optima, the iteration bound has a closed-form expression
- For LP instances with unique optima, PDHG has faster local convergence after identifying the optimal basis
- PDHG is polynomial-time with high probability

Remark:

- These results relied only on PDHG's average iterate convergence and non-expansiveness properties. Similar results might also hold for other FOMs, in particular ADMM, EGM, …

Thank you!
