## S1 Methods

**Sensitivity of emissions to emissions factors changes.** We conducted three additional simulations to examine the sensitivity of emissions in the No Policy scenario to emissions factors changes. First, we keep emissions factors fixed at their 2015 level. A comparison between this simulation and the No Policy scenario is shown in Figure S1. Without emissions factors changes, No Policy emissions show large increases: BC is 95% higher, and OC is 140% higher in 2030, reflecting the absence of existing policies aimed at reducing biomass burning in agricultural areas. Other pollutant species also show substantial increases by 2030: 59% for  $\text{SO}_2$ , 21% for  $\text{NO}_x$ , and 29% for  $\text{NH}_3$ . A second and third scenario double and triple, respectively, the emissions decay factors. We find that  $\text{SO}_2$  emissions fall by 36% and 58%,  $\text{NO}_x$  emissions fall by 14% and 25%,  $\text{NH}_3$  emissions by 20% and 35%, BC by 26% and 42%, and OC by 13% and 22% in the No Policy scenario by 2030, in the two respective cases.

## S2 Regional Outcomes

We report the full set of regional difference between the No Policy and 4% Policy in consumption, energy use,  $\text{CO}_2$  emission, and  $\text{PM}_{2.5}$  concentration in 2030 in Figures S3 and S4. Percentage changes of total  $\text{PM}_{2.5}$  and anthropogenic  $\text{PM}_{2.5}$  with respect to percentage changes of  $\text{CO}_2$  emission are shown in Figure S5. Table S5 lists avoided mortalities in each province under the 4% Policy, and the net benefit by taking the difference between the policy cost and monetized health benefit. The provinces are sorted based on GDP per capita in 2010, as a proxy for average household wealth.

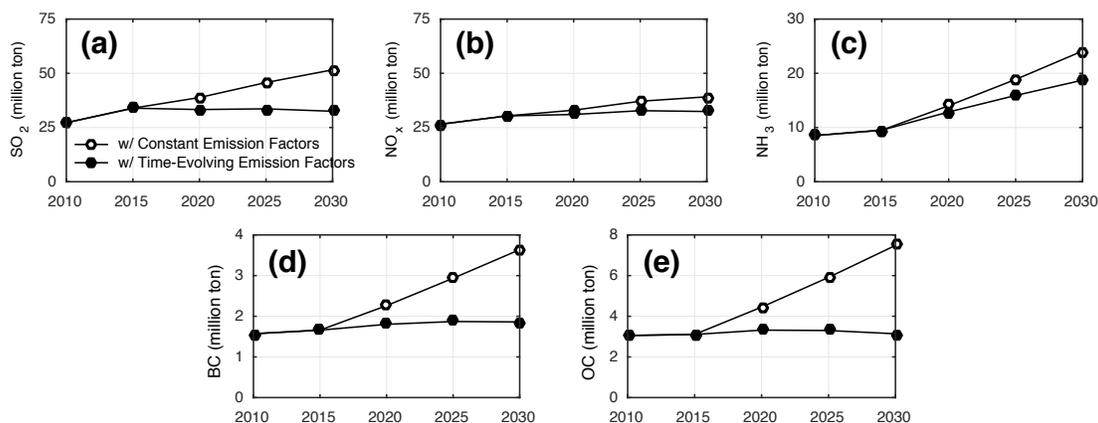

Figure S1: Comparison of emissions trajectories with time-evolving emissions factors and constant emissions factors.

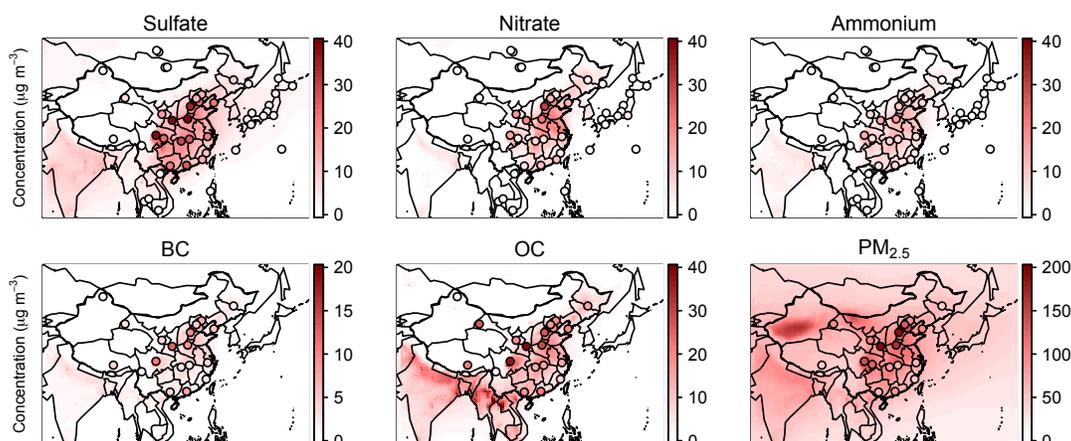

Figure S2: Simulated annual mean surface concentrations in East Asia for the year 2010 (sulfate, nitrate, ammonium, BC, OC, and total  $\text{PM}_{2.5}$ ). Circles indicate locations and concentrations of measurements used for model comparison.

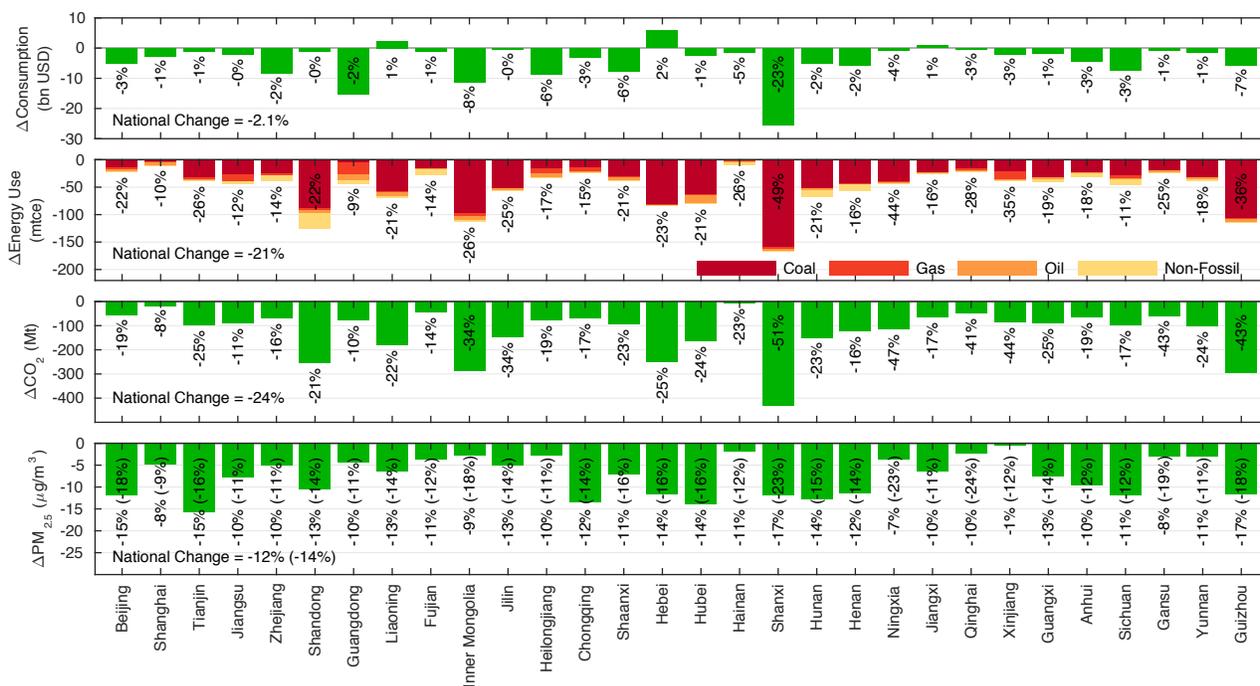

Figure S3: Changes in multiple outcomes due to the 4 % Policy, compared to the No Policy scenario in 2030. From top to bottom: consumption, energy use,  $\text{CO}_2$  emission, and population-weighted total  $\text{PM}_{2.5}$  concentration. Numbers beside each bar represent percentage changes, and numbers inside the parentheses in the bottom panel are percentage changes in terms of anthropogenic  $\text{PM}_{2.5}$ .

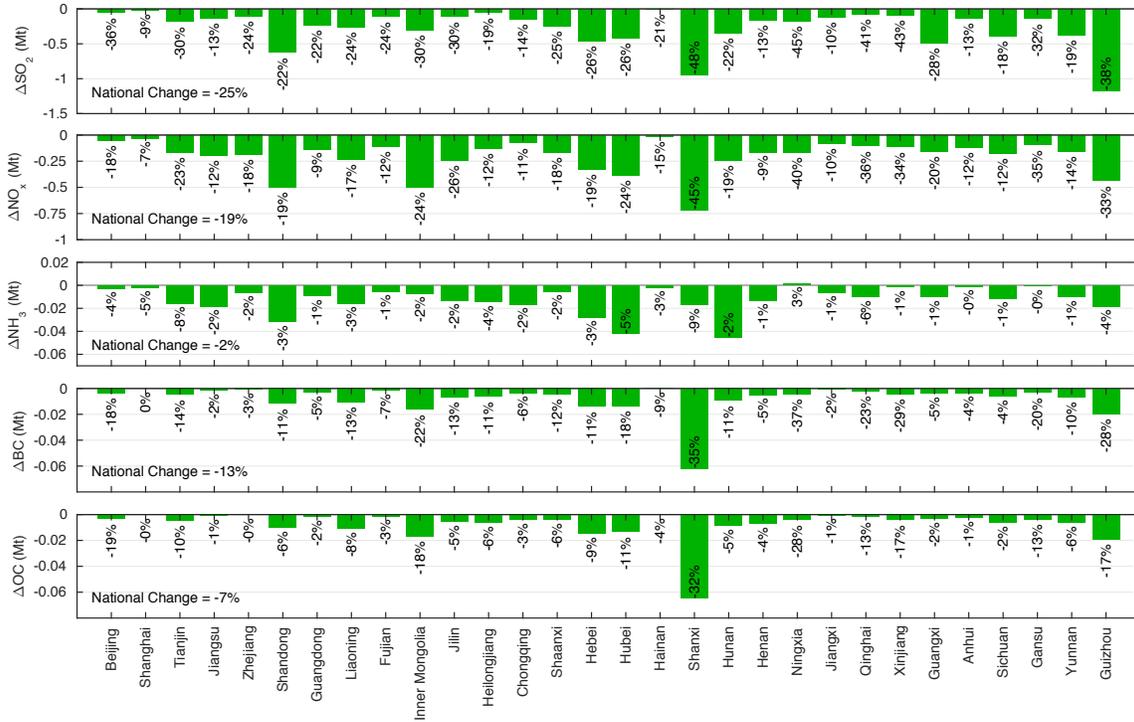

Figure S4: Changes in precursor emissions due to the 4 % Policy, compared to the No Policy scenario in 2030. Numbers beside each bar represent percentage changes.

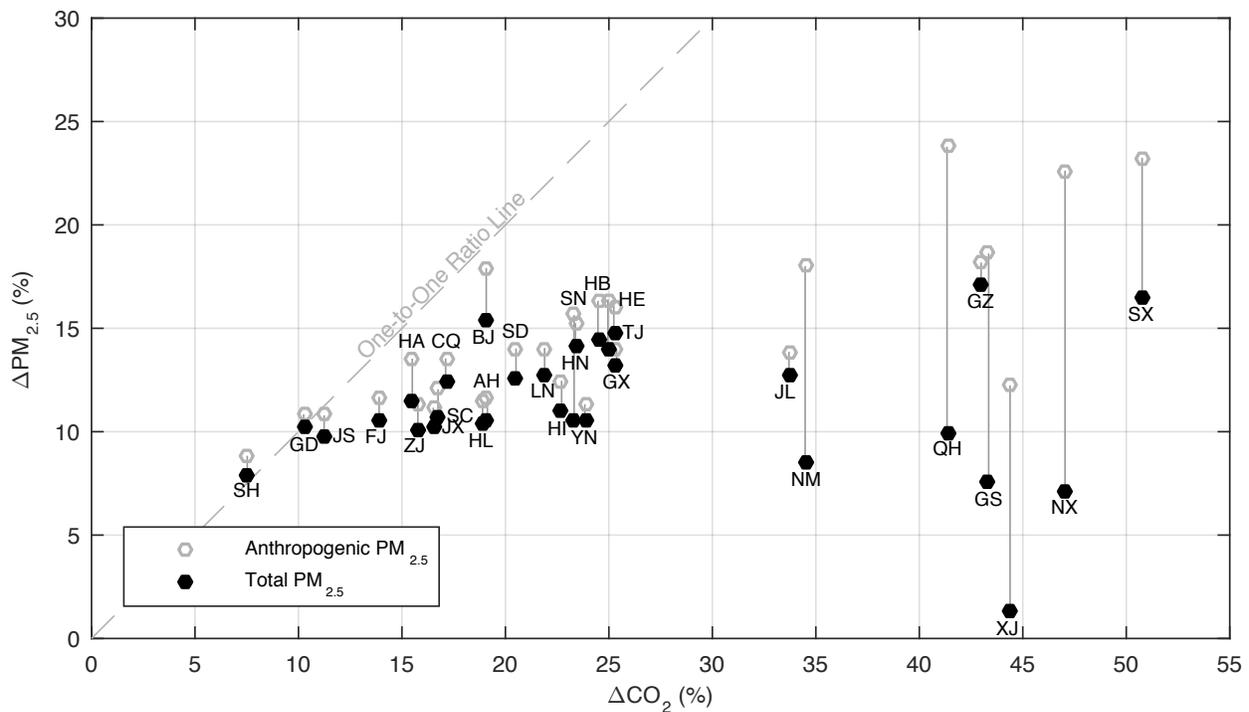

Figure S5: Percentage changes of PM<sub>2.5</sub> vs. CO<sub>2</sub> due to the 4% Policy, compared to the No Policy scenario in 2030.

Table S1: Regional and sectoral aggregation in C-REM

| <b>Regional</b>                       | <b>Sectoral (description in parenthesis)</b>        |
|---------------------------------------|---|
